project description:

Users will have pieces of song lyrics in mind. so, when they want to get the lyrics of the song. They should search. We are solving the problem using our retrieval model. User will give query having broken lyrics , we will recommend them list of lyrics similar to that lyrics.

Then our search engine will take the query and calculate similarity using vector space model and gives top 10 results. Also can refine results if it is given with user feedback.

1. Indexing components

we take the all documents and create a dictionary ,keys are the all unique words and posting list is document ID and frequency of that word in that document.

2. Searching components

we calculate the tf and idf values and assign the weights to the each document by creating vector.similarly find vector to query,now find the similarity between query and each document by using cosine similarity ,based on that we rank the document and return the top 10 document.

3. Refining searches based on specific filters

a. Search based on genre

we search the documents based on the genre of each document , in our data set we have only 7 genres ,if user enter the genre we return the top 10 documents based on the entered genre and similarity of that document

b. Search based on artist name

we search the documents based on artist name,if user enter any artist we return the documents related to the artist name

4. Capturing Feedback

By taking the relevance feedback from user, we find the new query using rocchio algorithm

$$(Q_{\text{new}} = \alpha(q) + \beta(u(R)) - \gamma(u(NR)))$$

$$\alpha = 1, \beta = 0.75, \gamma = 0.25$$

after getting new query we find cosine similarity between the new query and each document and return the top 10 documents

5. Assessment Components

we calculate the Precision, Recall and avgP and plot graph of Precision and Recall

Indexing and first round of search results
